25 **II. Supplementary Results and Discussion**

26 **III. References.**

## 28 **I. Experimental Procedure:**

### 29 **1. Chemicals**

30 The BC pellicles with fiber content of ~0.5 wt% were generated by a acetobacter xylinum  
31 fermentation process. All other chemicals were analytical grade and used as received without  
32 further purification. All aqueous solutions were prepared with ultrapure water (>18.2 MΩ cm)  
33 from a Milli-Q Plus system (Millipore). All glassware used in the following procedures were  
34 cleaned in a bath of freshly prepared HCl:HNO<sub>3</sub> (3:1) and rinsed thoroughly with ultrapure  
35 water prior to use.

### 36 **2. Preparation of carbon nanofiber foam (CNFF)**

37 The BC pellicles were purified by soaking in 0.2 mol L<sup>-1</sup> NaOH 60 °C for 2h and then rinsed  
38 several times in deionized water for five days. Then, the pellicles were cut into rectangular  
39 shape (50 mm×40 mm×18 mm), frozen by liquid nitrogen, and then freeze-dried for 72 h to  
40 obtain the BC aerogel.<sup>[1]</sup> The obtained BC aerogels were transferred into a tube furnace for  
41 carbonization under nitrogen atmosphere. The BC precursors were heated to 240 °C at a heating  
42 rate of 2 °C min<sup>-1</sup>, dwelled at 240 °C for 2 h, then heated to 1000 °C at 5 °C min<sup>-1</sup> and dwelled  
43 at 1000 °C for 2 h to allow complete pyrolysis, and then cooled down to room temperature  
44 naturally to yield compressible CNFF.

### 45 **3. Preparation of freestanding graphene film (FGF)**

46 FGF was prepared by exfoliating the nature graphite foil based on our previous work. Typically,  
47 graphite foil exfoliation was performed in a homemade two electrode system, whereby graphite  
48 foils were used as working anodes and Cu foils as counter electrodes. The electrolyte for the  
49 graphite exfoliation was prepared by dispersing ammonium sulfate (0.1 M) in DI water. The  
50 electrochemical exfoliation of graphite foil was carried out by applying constant positive  
51 voltage (+10 V) on the working electrode. The graphene powder was first collected with  
52 cellulose filters and washed repeatedly with DI water and ethanol by vacuum filtration. The  
53 washing process was repeated several times to clear any chemical residues. Then, the resultant  
54 graphene powder was dispersed in IPA by sonication for 5 h in an ice bath. The dispersion was

55 kept for 24 h for the precipitation of un-exfoliated graphite flakes. The top part of the dispersion  
56 was determined the concentration using the vacuum filtration method. After that, the graphene  
57 dispersion was filtered through polyamide membrane filters to obtain a thin film by vacuum-  
58 assisted filtration. Then, the film was dried at room temperature and peeled off from the  
59 polyamide membrane, which was denoted as FGF.

#### 60 **4. Electrochemical Measurements**

61 The electrochemical performances were conducted using the CR2032 coin type half-cells. The  
62 as-prepared CNFF were punched into circular electrodes with a diameter of 6.5 mm and  
63 directly used as the working electrodes, and K foil was used as both the counter and reference  
64 electrodes. The electrolyte used was a 1.0 M KPF<sub>6</sub> in a mixed solution of ethylene carbonate  
65 (EC), dimethyl carbonate (DMC) and ethylmethyl carbonate (EMC) with a volume ratio of  
66 4:3:2. The glass fiber (GF/D) from Whatman was used as the separator. The cells were  
67 assembled in an Ar-filled glove box with moisture and oxygen content of less than 0.1 ppm.  
68 After cycling tests, batteries were disassembled in the glove box and electrodes were washed  
69 with dimethyl carbonate (DMC) completely before being tested. Galvanostatic charge and  
70 discharge tests were carried out using a LAND-CT2011A battery-testing instrument at room  
71 temperature under different current densities in a voltage range of 0.01-2.8 V vs. K<sup>+</sup>/K. Cyclic  
72 voltammetry measurements were conducted at a scan rate of 0.1 mV s<sup>-1</sup> and electrochemical  
73 impedance measurements (EIS) were performed in the frequency range from 100 kHz to 0.01  
74 Hz on Biological SP150 Electrochemical Workstation at room temperature.

#### 75 **5. Sample characterization instruments**

76 The morphology of the CNFF was characterized by the scanning electron microscopy (SEM)  
77 (Hitachi S4800) and transmission electron microscopy (TEM) (JEOL 1010). High-resolution  
78 transmission electron microscopy (HRTEM) and energy dispersive X-ray spectroscopy (EDX)  
79 measurements were performed on a JEOL 2010F (Tokyo, Japan) HRTEM at an acceleration  
80 voltage of 200 kV. The samples for TEM images were prepared by dropping the dilute colloidal  
81 suspension (~0.05 mg mL<sup>-1</sup>) onto a copper grid and dried in ambient air at room temperature.  
82 The SEM images were obtained using a field-emission gun SEM (Quanta 400 FEG FEI) at an

83 accelerating voltage of 3.0 kV. X-ray diffraction (PANalytical/Philips X'Pert Pro) patterns of  
84 CNNF were recorded for  $2\theta$  -values ranging from  $10^\circ$  to  $60^\circ$  with Cu  $K\alpha$  radiation. Raman  
85 spectroscopy was carried out on a LabRam HR800 UV NIR with a 532 nm laser excitation.  
86 The nitrogen adsorption-desorption measurements were performed on a Quantachrome  
87 ASiQwin-Autosorb Iq Station 2 and the bath temperature was 77.35K (The outgas Temp. is  
88 453.15K). The compression tests were performed on an Instron 5565A testing machine  
89 equipped with 500-N and 10000-N compression stages. The strain rate was set at  $20 \text{ mm min}^{-1}$   
90 <sup>1</sup> for the tests. The specific surface area was calculated at 77 K using BET method.<sup>[2]</sup>
